ABSTRACT

In the full-length image capture mode, a background of a captured image includes not only a background curtain but also the periphery. The image to be edited from multiple captured images is selected, and the brightness of the image is adjusted. After that, a range to be edited of the background is calculated from the background of the image through Chromakey processing. Then, the color corresponding to the degree of the brightness of the adjusted image is obtained from the stored colors of the background curtain. The calculated editing range of the background is then converted with the obtained color. As a result, the boundary of the background curtain and the periphery becomes inconspicuous, and the image having a good-looking background can be provided easily.
